# Chapter 1

## Functions

### 1.1 prime – primality test , prime generation

#### 1.1.1 trialDivision – trial division test

**trialDivision(n: *integer*, bound: *integer/float=0*) → *True/False***

Trial division primality test for an odd natural number.

**bound** is a search bound of primes. If it returns 1 under the condition that **bound** is given and less than the square root of **n**, it only means there is no prime factor less than **bound**.

#### 1.1.2 spsp – strong pseudo-prime test

**spsp(n: *integer*, base: *integer*, s: *integer=*None, t: *integer=*None)  
→ *True/False***

Strong Pseudo-Prime test on base **base**.

**s** and **t** are the numbers such that  $n - 1 = 2^s t$  and **t** is odd.

#### 1.1.3 smallSpsp – strong pseudo-prime test for small number

**smallSpsp(n: *integer*) → *True/False***

Strong Pseudo-Prime test for integer **n** less than  $10^{12}$ .

4 spsp tests are sufficient to determine whether an integer less than  $10^{12}$  is prime or not.

#### 1.1.4 `miller` – Miller’s primality test

`miller(n: integer) → True/False`

Miller’s primality test.

This test is valid under GRH. See `config`.

#### 1.1.5 `millerRabin` – Miller-Rabin primality test

`millerRabin(n: integer, times: integer=20) → True/False`

Miller’s primality test.

The difference from `miller` is that the Miller-Rabin method uses fast but probabilistic algorithm. On the other hand, `miller` employs deterministic algorithm valid under GRH.

`times` (default to 20) is the number of repetition. The error probability is at most  $4^{-\text{times}}$ .

#### 1.1.6 `lpsp` – Lucas test

`lpsp(n: integer, a: integer, b: integer) → True/False`

Lucas Pseudo-Prime test.

Return True if `n` is a Lucas pseudo-prime of parameters `a`, `b`, i.e. with respect to  $x^2 - ax + b$ .

#### 1.1.7 `fpsp` – Frobenius test

`fpsp(n: integer, a: integer, b: integer) → True/False`

Frobenius Pseudo-Prime test.

Return True if `n` is a Frobenius pseudo-prime of parameters `a`, `b`, i.e. with respect to  $x^2 - ax + b$ .

#### 1.1.8 `apr` – Jacobi sum test

`apr(n: integer) → True/False`

APR (Adleman-Pomerance-Rumery) primality test or the Jacobi sum test.

Assuming `n` has no prime factors less than 32. Assuming `n` is spsp (strong pseudo-prime) for several bases.

### 1.1.9 `primeq` – primality test automatically

`primeq(n: integer) → True/False`

A convenient function for primality test.

It uses one of `trialDivision`, `smallSpsp` or `apr` depending on the size of `n`.

### 1.1.10 `prime` – $n$ -th prime number

`prime(n: integer) → integer`

Return the `n`-th prime number.

### 1.1.11 `nextPrime` – generate next prime

`nextPrime(n: integer) → integer`

Return the smallest prime bigger than the given integer `n`.

### 1.1.12 `randPrime` – generate random prime

`randPrime(n: integer) → integer`

Return a random `n`-digits prime.

### 1.1.13 `generator` – generate primes

`generator((None)) → generator`

Generate primes from 2 to  $\infty$  (as generator).

#### 1.1.14 generator\_eratosthenes – generate primes using Eratosthenes sieve

**generator\_eratosthenes**(n: *integer*) → *generator*

Generate primes up to **n** using Eratosthenes sieve.

#### 1.1.15 primonial – product of primes

**primonial**(p: *integer*) → *integer*

Return the product

$$\prod_{q \in \mathbb{P} \leq p} q = 2 \cdot 3 \cdot 5 \cdots p .$$

#### 1.1.16 properDivisors – proper divisors

**properDivisors**(n: *integer*) → *list*

Return proper divisors of **n** (all divisors of **n** excluding 1 and **n**).

It is only useful for a product of small primes. Use **proper\_divisors** in a more general case.

The output is the list of all proper divisors.

#### 1.1.17 primitive\_root – primitive root

**primitive\_root**(p: *integer*) → *integer*

Return a primitive root of **p**.

**p** must be an odd prime.

#### 1.1.18 Lucas\_chain – Lucas sequence

**Lucas\_chain**(n: *integer*, f: *function*, g: *function*, x\_0: *integer*, x\_1: *integer*) → (*integer*, *integer*)

Return the value of  $(x_n, x_{n+1})$  for the sequence  $\{x_i\}$  defined as:

$$\begin{aligned}x_{2i} &= \mathbf{f}(x_i) \\ x_{2i+1} &= \mathbf{g}(x_i, x_{i+1}) ,\end{aligned}$$

where the initial values  $\mathbf{x}_0, \mathbf{x}_1$ .

$\mathbf{f}$  is the function which can be input as 1-ary integer.  $\mathbf{g}$  is the function which can be input as 2-ary integer.

### Examples

```
>>> prime.primeq(131)
True
>>> prime.primeq(133)
False
>>> g = prime.generator()
>>> g.next()
2
>>> g.next()
3
>>> prime.prime(10)
29
>>> prime.nextPrime(100)
101
>>> prime.primitive_root(23)
5
```
